# Chapter 1

## Antennas

### 1.1 Antennas Parameters

#### 1.1.1 Directive Gain

The power radiated by an antenna depends on the direction. The *directive gain* toward a given direction is expressed as:

$$D(\theta, \phi) = \frac{\text{Radiation Intensity}}{\text{Isotropic Intensity}} = \frac{U(\theta, \phi)}{P_{\text{rad}}/4\pi} \quad (1.1)$$

#### 1.1.2 Radiated Power Density

It is useful to evaluate the radiated power density as it can be used for an analysis of propagation of power towards the three-dimensional space.

$$S_R = \frac{dP_{\text{rad}}}{ds} = \frac{1}{2} \text{Re}(E \times H^*) = \frac{1}{R^2} U(\theta, \phi) \quad (1.2)$$

#### 1.1.3 Received Power

Figure 1.1: Simplified scheme of a Radio Link with an additional power density from a non optimal direction

Given the power density ( $S_R$ )<sup>1</sup> and the direction of arrival ( $\theta$ ) of an incident radiation the received power can be calculated as:

$$A_e S_R f(\theta) \quad (1.3)$$

---

<sup>1</sup>magnitude of the Poynting vector

where:

- $A_e$  is the **effective Area** of the antenna
- $f(\theta)$  is the directivity function

#### 1.1.4 Effective Area

$$\frac{G}{A_e} = \frac{4\pi}{\lambda^2} \quad (1.4)$$

#### 1.1.5 Equivalent length

The equivalent length can be related to the effective area using the following formula:

### 1.2 Radio Link

#### 1.2.1 Link Budget

Figure 1.2: Simplified scheme of a Radio Link

Supposing to have a Radio Link as in Figure 1.2 between 2 Antennas at a certain relative distance  $R$  the link budget may be evaluated by means of the **Friis equation** which at the end leads to a simple analytical expression for the receiving power<sup>2</sup>:

$$P_{r|dB} = P_{t|dB} - 10 \log \frac{\lambda}{4\pi R} + G_{t|dB} + G_{r|dB} \quad (1.5)$$

in which:

- $P_{r|dB}$  is the effective power received by the antenna.
- $P_{t|dB}$  is the overall transmitted power of the TX side.
- $G_{r|dB}$  is the gain of the receiving antenna.
- $G_{t|dB}$  is the gain of the transmitting antenna.

while the term  $20 \log \frac{\lambda}{4\pi R}$  stands for the free space losses. Note from a practical point of view there as at least a couple of DoF in the design flow to obtain a certain receiving power.

We may also report the linear form of the **Friis equation**:

$$P_r = P_t \left( \frac{\lambda}{4\pi L} \right)^2 G_T G_R \quad (1.6)$$

---

<sup>2</sup>which is the logarithmic form of the Friis equation

### 1.2.2 Attenuators' Noise

In any RF receiver we are going to have at least some losses between the antenna and the LNA. Sometimes also in other sections of the receiver path attenuation couldn't be avoided. We may evaluate the additional noise introduced by an attenuator  $A_{f1}$  for example the one in Figure 1.3 as:

$$T_{f1} = T_0(10^{\frac{A_{f1}}{10}} - 1) \quad (1.7)$$

### 1.2.3 Equivalent Temperature

Figure 1.3: General structure of a noisy receiving chain

Supposing to have a receiving chain as in Figure 1.3 we may want to represent the system with noiseless components and an input referred noise considering all contribution. This could be very useful because using this model the Signal-to-Noise Ratio evaluation turns out to be extremely simple, while we can just compare the receiving power with the overall noise directly at the input port.

To get an  $T_{equivalent}$  we have to refer at the input any additional noise by dividing it by the Gain from the input to the point where the noise is injected.

At the end for the example in figure we get:

$$T_{sys} = T_{eq} = T_a + T_{f1} + T_{LNA}A_{f1} + T_{f2}\frac{A_{f1}}{G_{LNA}} + T_{SSB}\frac{A_{f1}A_{f2}}{G_{LNA}} \quad (1.8)$$

where:

- $T_{f1}$  is the noise introduced by the first attenuator
- $T_{LNA}$  is the noise introduced by the LNA
- $T_{f2}$  is the noise introduced by the second attenuator
- $T_{SSB}$  is the noise introduced by the mixer

With the same concept we may find the *Output Referred Noise*  $T_{out}$  by simply applying the relative transfer function at each noise to the output:

$$T_{out} = T_a\frac{G_{LNA}}{A_{f1}A_{f2}} + T_{f1}\frac{G_{LNA}}{A_{f1}A_{f2}} + T_{LNA}\frac{G_{LNA}}{A_{f2}} + T_{f2}\frac{1}{A_{f2}} + T_{SSB} \quad (1.9)$$

<sup>3</sup>note that here  $A_x$  stands for an attenuation =  $\frac{1}{G_{ain}}$  and G stands for a Gain

and to get  $T_{eq}$  we may divide  $T_{out}$  by the noiseless gain  $\frac{G_{LNA}}{A_{f1}A_{f2}}$

$$T_{eq} = \frac{T_{out}}{\frac{G_{LNA}}{A_{f1}A_{f2}}} \quad (1.10)$$

after some algebra it's clear that the two different approaches are absolutely equivalent.

#### 1.2.4 Noise Figure

The Noise Figure is very usefull as it gives an immediate evaluation of the overall degradation that a system gives to the SNR.

Noise Figure is usually calculate diving the overall noise of the system by the noise given by the source; this operation is usually done at the output but can be done in every point of the system.

#### 1.2.5 Noise figue and equivalent temperature relationship

$$T_{eq} = T_0(10^{\frac{NF_{eq}}{10}} - 1) \quad (1.11)$$

where  $T_0$  it's usually the room temperature considered  $290^\circ C$ .

#### 1.2.6 Datarate Limitation

Given the modulation and demodulation scheme<sup>4</sup>, the bandwidth (B) and the minimum SNR required the maximum possible datarate (R) is limited by noise.

Known the equivalent noise temperature ( $T_{eq} = T_{sys}$ ) e can write:

$$SNR = \frac{P_r}{KT_{sys}B} = \left(\frac{E_b}{N_0}\right) \left(\frac{R}{B}\right) \quad (1.12)$$

---

<sup>4</sup>Given the mod/demod scheme the energy transmitter per bit is fixed

## Chapter 2

# Receivers

### 2.1 Image

The problem of the image rises during the demodulation process when the RF signal is downconverted to an Intermediate Frequency (IF) because of the mixer by means of the LO downconverts to IF both the RF signal and the Image which any signal at the same opposite distance<sup>1</sup> from the LO with respect to RF signal.

#### Example

Let's report an example for clarification<sup>2</sup>:

- $f_{RF} = 12\text{GHz}$
- $f_{IF} = 140\text{MHz}$

we know that the local oscillator frequency ( $f_{LO}$ ) is above the signal band.  
Find the frequency of the image is quite simple:

$$f_{IF} = |f_{RF} - f_{LO}| \quad (2.1)$$

from this we are able to find  $f_{LO}$  and then:

$$f_{IM} = f_{LO} - f_{IF} = f_{RF} - 2f_{IF} \quad (2.2)$$

### 2.2 Cascaded Noise Figure

The evaluation of the Noise figure of cascaded stage could be performed with this formula:

$$NF_{eq} = NF_1 + \frac{NF_2 - 1}{G_1} + \frac{NF_3 - 1}{G_1 G_2} \quad (2.3)$$

---

<sup>1</sup>Note that this distance is by definition IF
